1 Part 1: Form a Dictionary and Word Frequency Count

Part one required me to implement the methods `formDictionary` and `saveToFile`. For the former, after trying a few different methods with different data structures I've settled on using a single hash table to store the dictionary, as this allows me to store both the word and its count as a pair. A hash table data structure also allows for a very good average time complexity for searching and inserting of $\theta(1)$ (constant time) while maintaining a decent space complexity of $O(n)$.

The design of `saveToFile` followed a similar path as `formDictionary`, whereby I experimented with designing and implementing many different solutions simultaneously with those of `formDictionary` before settling on what I feel is the most efficient implementation. This final version takes the key-value pairs one by one from the hash table previously mentioned, forms a string from them and adds them to a list data structure. This list is then sorted and sent to the `saveCollectionToFile` method given.

In addition to the above methods, `DictionaryFinder` also contains `readWordsFromCSV`, which produces a list from a given CSV format file.

Algorithm 1 `formDictionary(A,l)` **return D**

Require: list **A** of length l containing strings.

Ensure: **D**, the dictionary formed from **A**.

```
1: D  $\leftarrow$  new map ▷ initialise map to store dictionary
2: for  $i \leftarrow 1$  to  $l$  do
3:   found  $\leftarrow$  false
4:   for each  $(k,v)$  pair  $\in$  D do
5:     if  $A_i := k$  then
6:        $v \leftarrow v + 1$  ▷ add one to the value on this entry
7:       found  $\leftarrow$  true
8:       break
9:   if found  $:=$  false then
10:    D  $\leftarrow (k \leftarrow A_i, v \leftarrow 1)$  ▷ add a new (k,v) pair to the map
return D
```

In analysing `formDictionary`, we see that the fundamental operations are ($v \leftarrow v + 1$, *found* \leftarrow , **break**). The case we are interested in is the worst case - Order O . The Runtime Complexity function is as follows - the three fundamental operations only occur if there is a match therefore only a check of the map entry happens every loop, and this happens within a loop. Therefore for any given value of l and for any size of map **D** (represented as m), we get

$$t_{formDictionary} = \sum_{i=1}^l \sum_{j=1}^m 1 \tag{1}$$

For solving the summations, we first remove the rightmost summation and apply the summation rule

$$\sum_{i=1}^p 1 = p \tag{2}$$

on the innermost loop to give m , which leaves

$$t_{formDictionary} = \sum_{i=1}^l m \tag{3}$$

Then we deal with the remaining summation using the rule

$$\sum_{i=1}^p a = a \sum_{i=1}^p 1 = ap \quad (4)$$

to get

$$t_{formDictionary} = lm \quad (5)$$

where $m \leq l$.

By characterising the above Runtime Function we find that the worst case for this algorithm is Order nm or $O(nm)$.

Algorithm 2 saveToFile(**D**)

Require: map **D**.

- 1: **A** \leftarrow new collection \triangleright initialise collection to store strings
 - 2: **for each** (k,v) pair \in **D** **do**
 - 3: $a \leftarrow k \& \text{,} \text{,} \& v$ \triangleright form string from k and v in requested format
 - 4: **A** $\leftarrow a$
 - 5: sort(**A**) \triangleright ensure A is sorted alphabetically with mergesort
 - 6: saveCollectionToFile(**A**, "A.csv") \triangleright pass collection into the provided method
-

In analysing saveToFile, we see that the fundamental operation is either $(a \leftarrow k \& \text{,} \text{,} \& v, \mathbf{A} \leftarrow a)$ or $\text{sort}(\mathbf{A})$, so we will start with analysis of the former. The case we are interested in is the worst case - Order O . The Runtime Complexity function is as follows - the two fundamental operations each happen once per loop of D . Forming a string is a single operation and the complexity of adding it to a collection is dependant on the collection used, so we will assume a Linked List which inserts in constant time. Therefore if we assign the size of D to be l we get

$$t_{saveToFile} = \sum_{i=1}^l 2 \quad (6)$$

The constant on the right can be collapsed and using the rule

$$\sum_{i=1}^p 1 = p \quad (7)$$

we get

$$t_{saveToFile} = l \quad (8)$$

By characterising this first Runtime Function candidate, we find that the worst case for this algorithm is Order n or $O(n)$. For the second candidate, we know that the best algorithm for sorting strings, mergesort, gives Order $n \log(n)$ worst-case performance, which is worse than Order n . Therefore from this analysis we can tell that the fundamental operation of the saveToFile algorithm is $\text{sort}(\mathbf{A})$ and that it's characterisation is $O(n \log(n))$.

2 Part 2: Implement a Trie Data Structure

Part two required the design and implementation of a Trie data structure comprised of TrieNodes to store a list of given words. Each node represents one character in a word and given words are chained together through storing lists of child nodes in each node. Methods were then written and implemented which store, split and recall words within the Trie. The TrieNode structure itself contains four variables:

1. *value* - This is a letter from a to z which this node represents.
2. *offspring* - This is a fixed list of 26 spaces, where each space can be assigned a child node representing a letter which would follow the current value in a given word.
3. *isKey* - This is a flag that is true when the current node is the end of a stored word and otherwise is false.
4. *level* - This is a number which shows how deep the current node is in the Trie structure.

The TrieNode also contains getter and setter methods, the following are the more complex examples of these:

- `getOffspring(TrieNode N, char c)` - We take 97 away from the ASCII value of c to get a numerical value between 0 and 25 for all letters of the alphabet, then if it exists, return the child node of N at that location in the offspring list.
- `getAllOffspring(TrieNode N)` - Add each node from N 's offspring list to a list and return it.
- `setOffspring(TrieNode N, char c)` - We take 97 away from the ASCII value of c and check the offspring list on N for an entry. If no entry exists we add a new node to the list and return true, otherwise we return false.

The Trie data structure holds only one variable, *root*, which is the address of the first TrieNode in the Trie and is assigned when the Trie is constructed. The Trie has a number of methods which control how nodes are added and manipulated within it. I will detail these in full below.

Algorithm 3 `add(T K,l) return f`

Require: Trie T , string K of length l .

Ensure: f , a flag indicating if K was added to the Trie or not.

```
1: TrieNode C ← K.root           ▷ initialise node C with the value of this Trie's root
2: f ← false
3: for i ← 1 to l do
4:   k ← Ki                       ▷ char k holds the value of the current character in K
5:   TrieNode N ← getOffspring(C, k)
6:   if N := null then
7:     setOffspring(C, k)
8:     N ← getOffspring(C, k)
9:     setLevel(N, i + 1)         ▷ call setter for level variable on node N
10:    f ← true
11:   C ← N
12: if C := not null then
13:   setKey(C)                   ▷ set the isKey flag on node C to true when the last letter of K is added
return f
```

Algorithm 4 contains(**T** **K**, l) **return** f

Require: Trie **T**, string **K** of length l .

Ensure: f , a flag indicating if **K** exists in **T** or not.

```
1: TrieNode C  $\leftarrow$  T.root
2:  $f \leftarrow false$ 
3: for  $i \leftarrow 1$  to  $l$  do
4:   char  $k \leftarrow \mathbf{K}_i$ 
5:   TrieNode N  $\leftarrow$  getOffspring(C,  $k$ )
6:   if N := null then return false
7:   C  $\leftarrow$  N
8:    $f \leftarrow$  getKey(C)            $\triangleright$  set the value of  $f$  to the value of node  $C$ 's getKey variable
return  $f$ 
```

Algorithm 5 outputBreadthFirstSearch(**T**) **return** **S**

Require: Trie **T**.

Ensure: **S**, a string of characters taken from reading the Trie breadth-first.

```
1: V  $\leftarrow$  new list
2:  $l \leftarrow 1000$ 
3: S  $\leftarrow$  new string with length of  $l$ 
4:  $p \leftarrow 0$                                 $\triangleright$  integer to hold position within  $S$ 
5: V.add(T.root)
6: while V := not empty do
7:   TrieNode C  $\leftarrow$  V.remove()
8:   S $_p \leftarrow$  C.value
9:   list L  $\leftarrow$  getAllOffspring(C)
10:  for each TrieNode N  $\in$  L do
11:    V.add(N)
12:   $p \leftarrow p + 1$ 
13:  if  $p := l$  then                              $\triangleright$  increase the length of  $S$  by a multiple of 10 if it's too short
14:    String E  $\leftarrow$  S
15:     $l \leftarrow l \times 10$ 
16:    S  $\leftarrow$  new string with length of  $l$ 
17:    for  $i \leftarrow 1$  to  $(l \div 10)$  do
18:      S $_i \leftarrow$  E $_i$ 
return S
```

Algorithm 6 outputDepthFirstSearch(**T**) return **S**

Require: Trie **T**.

Ensure: **S**, a string of characters taken from reading the Trie breadth-first.

```
1: V  $\leftarrow$  new stack
2:  $l \leftarrow 1000$ 
3: S  $\leftarrow$  new string with length of  $l$ 
4:  $p \leftarrow 0$ 
5: V.push(T.root)
6: while V := not empty do
7:   TrieNode C  $\leftarrow$  V.pop()
8:   list L  $\leftarrow$  getAllOffspring(C)
9:    $m \leftarrow$  (length of N) - 1
10:  while L := not empty do
11:    V.push(N.get( $m$ ))
12:     $m \leftarrow m - 1$ 
13:  S $p$   $\leftarrow$  C.value
14:   $p \leftarrow p + 1$ 
15:  if  $p := l$  then  $\triangleright$  increase the length of  $S$  by a multiple of 10 if it's too short
16:    String E  $\leftarrow$  S
17:     $l \leftarrow l \times 10$ 
18:    S  $\leftarrow$  new string with length of  $l$ 
19:    for  $i \leftarrow 1$  to  $(l \div 10)$  do
20:      S $i$   $\leftarrow$  E $i$ 
return S
```

Algorithm 7 getSubTrie(**T** **P**, l) return **U**

Require: Trie **T**, string **P** of length l .

Ensure: **U**, the Subtrie rooted at **P**.

```
1: U  $\leftarrow$  new Trie
2: TrieNode S  $\leftarrow$  T.root
3: if P := empty then return U
4: for  $i \leftarrow 1$  to  $l$  do
5:    $c \leftarrow \mathbf{P}_i$ 
6:   TrieNode N  $\leftarrow$  getOffspring(S,  $c$ )
7:   if N := null then return S
8:   S  $\leftarrow$  N
9: U.root  $\leftarrow$  S return U
```

Algorithm 8 getAllWords(**T**) return **L**

Require: Trie **T****Ensure:** **L**, a list of strings formed from **T**.

```
1: L  $\leftarrow$  new list
2: V  $\leftarrow$  new stack
3:  $l \leftarrow 35$   $\triangleright$  maximum length of an expected word
4: S  $\leftarrow$  new string of length  $l$ 
5: list O  $\leftarrow$  getAllOffspring(T.root)
6:  $m \leftarrow$  (length of O)  $- 1$ 
7: while O := not empty do
8:   V.push(O.get( $m$ ))
9:    $m \leftarrow m - 1$ 
10: while V := not empty do
11:   TrieNode C  $\leftarrow$  V.pop()
12:    $p \leftarrow$  C.level + 1  $\triangleright$  position of the next character
13:   S $p$   $\leftarrow$  C.value
14:   if C.isKey := true then
15:     F  $\leftarrow$  new string
16:     for  $i \leftarrow 1$  to  $p$  do
17:       F  $\leftarrow$  F + S $i$ 
18:     L.add(F)
19:   O  $\leftarrow$  getAllOffspring(C)
20:    $m \leftarrow$  (length of O)  $- 1$ 
21:   while O := not empty do
22:     V.push(O.get( $m$ ))
23:      $m \leftarrow m - 1$ 
return L
```

3 Part 3: Word Auto Completion Application

The following main() algorithm relies on the data structures and algorithms explained in parts 1 and 2.

Algorithm 9 main()

```
1:                                     ▷ 1. form a dictionary file of words and counts from the file lotr.csv.
2: D ← new DictionaryFinder
3: list L ← readWordsFromCSV(D, "lotr.csv")
4: D.formDictionary(L)
5:                                     ▷ 2. construct a trie from the dictionary using your solution from part 2.
6: T ← new Trie
7: for each (k,v) pair ∈ D do
8:   T.add(k)
9:                                     ▷ 3. load the prefixes from lotrQueries.csv
10: list P ← readWordsFromCSV("lotrQueries.csv")
11:                                     ▷ 4. for each prefix query:
12: F ← new list                                     ▷ list to store strings to be saved to file
13: for each p ∈ P do
14:                                     ▷ 4.1. Recover all words matching the prefix from the trie.
15:   Trie S ← getSubTrie(T, p)
16:   list M ← getAllWords(S)
17:                                     ▷ 4.2. Choose the three most frequent words and display to standard output.
18:   C ← new list                                     ▷ list of lists to store frequency and position of words found
19:   c ← 0
20:   if D.contains(p) then
21:     M.add("")
22:   l ← size of M
23:   for i ← 1 to l do
24:     string a ← p+ M.get(i)
25:     b ← D.get(a) ▷ retrieve from dictionary the value for key matching the above string
26:     c ← c + b
27:     E ← new list
28:     E.add(b)
29:     E.add(i)
30:     C.add(E)
31:   while C := unsorted do
32:     using mergesort sort C where C.get(i).get(1) > C.get(i + 1).get(1)
33:   string H ← p
34:   for i ← 1 to l and i < 4 do
35:     z ← C.get(i).get(1) ÷ c
36:     Y ← p+ M.get(C.get(i).get(2))
37:     print Y + " (probability " + z + ")"                                     ▷ see below for console output
38:     H ← H + "," + Y + "," + z
39:   F.add(H)
40:   print ""
41:                                     ▷ 4.3. Write the results to lotrMatches.csv.
42: saveCollectionToFile(F, "lotrMatches.csv")
```

4 Code Listing

Listing 1: DictionaryFinder.java

```
1  /*****
2
3  Project      : CMP-5014Y - Word Auto Completion with Tries:
4                AutoCompletion.
5
6  File        : DictionaryFinder.java
7
8  Date        : Friday 06 March 2020
9
10 Author       : Martin Siddons
11
12 Description  : This class fulfills the requirements of part 1. It
13                ↪ supplies
14 methods that read in a text document into a list of Strings, form a
15                ↪ set of
16 words that exist in the document and count how many times each word
17                ↪ occurs,
18 sort the list alphabetically and write those words and frequencies
19                ↪ to file.
20
21 History      :
22 06/03/2020 - v1.0 - Initial setup, copied over readWordsFromCSV and
23 saveCollectionToFile.
24 07/03/2020 - v1.1 - Eventually settled on a implementation that
25                ↪ works well in
26 Java. Editing pseudocode to fit.

3  Project      : CMP-5014Y - Word Auto Completion with Tries :
4                AutoCompletion.
5
6  File         : Trie.java
7
8  Date         : Thursday 12 March 2020
9
10 Author       : Martin Siddons
11
12 Description  : Part 2 of the assignment is to make a Trie Data
13                ↳ Structure to
14                hold strings and write methods to manipulate the trie.
15
16 History      : 12/03/2020 - Initial setup
17                14/03/2020 - Completed Q1.
18                13/05/2020 - Lost track on filling this in, just finished Q2.
19                14/06/2020 - Fixed implementation of getAllWords for part 3.
20                15/06/2020 - Finalised implementation by clearing up some methods.
